Good News and Bad News about Monopoles

In general, static magnetic fields are much stronger than static electric fields. The Lorentz electromagnetic force law

$$\mathbf{F} = q (\mathbf{E} + \mathbf{v} \times \mathbf{B}) \quad (\text{SI})$$

tells us that a 1 Tesla magnetic field exerts the same force on a relativistic particle ($v \approx c$) as a 3×10^8 Volt/metre electric field. This can also be seen from the units, *i.e.*

$$1 \text{ Volt/metre} = 1 \text{ (metre/second)Tesla}$$

Using the conversion constant $c = 3 \times 10^8$ m/s, we have $1\text{m/s} = 1/(3 \times 10^8)$, so

$$3 \times 10^8 \text{ Volt/metre} = 1 \text{ Tesla}$$

It is easy to generate a 10T ($= 3 \times 10^3$ MV/m) static magnetic field, but static electric fields above about 3 MV/m are almost impossible. This is because our world is made from particles with electric charge but no magnetic charge, so high electric fields are shorted out by sparks consisting of electrically charged particles. There is no known reason why magnetic charges ("magnetic monopoles") should not exist, and they probably do but very rarely and with masses of the order of 10^{15} GeV/c².

e.g. The complete Lorentz force law is

$$\mathbf{F} = q_e (\mathbf{E} + \mathbf{v} \times \mathbf{B}) + q_m (\mathbf{B} + \mathbf{v} \times \mathbf{E}) \quad (\text{signs?})$$

Synchrotrons

- ring of magnets
- small amount of radiofrequency (r.f.) acceleration
- magnetic field increases synchronously with beam

momentum $B = \frac{p}{|q|r}$

Example: **Fermilab Tevatron**

- $r = 1 \text{ km}$
 - $B = 0 - 5 \text{ Tesla}$
 - $\Delta E/\text{orbit} \sim 3 \text{ MeV} (10\text{m} @ 1/3 \text{ MV/m})$
- $\Rightarrow E_{\text{final}} = 1 \text{ TeV}$ (protons, antiprotons)

Effective Accelerating Gradient

$$G = \frac{\text{final particle energy}}{\text{length of accelerator}}$$

for a synchrotron

$$G = \frac{E_{\text{max}}}{2\pi r} \approx \frac{p_{\text{max}} c}{2\pi r} \quad (E \gg m)$$

$$\therefore G \text{ (J/m)} = \frac{|q|cB_{\text{max}}}{2\pi} \quad (\text{SI})$$

$$\begin{aligned} \therefore G \text{ (eV/m)} &= \frac{|q|ecB_{\text{max}}}{2\pi} \\ &= \left(48 \frac{\text{MeV/m}}{\text{Tesla}}\right) \cdot B_{\text{max}} \end{aligned}$$

e.g.

Tevatron: $G \sim 150 \text{ MeV/m}$,

LHC: $G \sim 250 \text{ MeV/m}$

LEP Copper RF

Acceleration by Electromagnetic Waves

Power per unit area of an electromagnetic wave (Poynting Vector)

$$\mathbf{P} = \mathbf{E} \times \mathbf{B} / \mu_0$$

In vacuum: $E_{\text{max}} = cB_{\text{max}}$, but E & B are 90° out of phase, so

$$P_{\text{rms}} = (E_{\text{rms}})^2 / c\mu_0$$

$$\therefore E_{\text{max}} = 2^{1/2} E_{\text{rms}} = (2P_{\text{rms}}\mu_0 c)^{1/2}$$

So the maximum electric field is

$$E_{\text{max}}(\text{V/m}) = 27.5 [P_{\text{rms}}(\text{W/m}^2)]^{1/2}$$

e.g. $10^{20} \text{ W/m}^2 \Rightarrow E_{\text{max}} = 275 \text{ GV/m}$

But in free space \mathbf{E} is transverse to the direction of propagation of the wave, so there can be no continuous acceleration, just oscillation.
