

Hard Scattering in Hadron-Hadron Collisions: Physics and Anatomy

Section 6: Neutrinos and Missing Transverse Energy

1. Philosophy of MET techniques
2. Instrumental strengths and compromises
3. Measurement techniques
4. Background considerations
5. Example: MET in SUSY events

Basic MET Philosophy

- UA1 pioneered “missing energy” technique to detect non-interacting particles
 - Build “hermetic” calorimeter
 - > Most hadrons interact in calorimeter
 - > EM objects also measured in calorimeter
 - Can identify and measure μ leptons separately
 - Correct for cracks, non-linear energy response
- Worked surprisingly well
 - Discovery of W boson

- Become essential to most measurements
 - Require it when expect a non-interacting particle in final state
 - Require little MET if one expects all particles to be observable

Measurement Techniques

- Usual strategy is to take “raw” energy in each cell i

- Compute vector MET

$$\vec{E}_T = - \sum_{i \text{ cal towers}} (E_T^i \vec{x} + E_T^i \vec{y}) \quad \text{and} \quad E_T \equiv |\vec{E}_T|$$

- Identify μ , jet candidates

- > For muons, identify energy deposition in calorimeter

- Subtract EM+Had deposition
- Add -ve of μ momentum to MET

- > For jets, identify jet objects

- Subtract ET of towers making up jet
- Add back in “corrected” jet energies

- Remaining “unclustered” energy

- > Correct on average for energy response

- Corrected MET thus depends on definition of other objects

- Resolution depends on “average” calorimeter resolution

$$\sigma(E_T) \approx k \sqrt{\sum E_T^i}$$

- But also varies with final state

- > Need to measure it
- > Example from W mass measurement

- Fit gives $k \sim 0.4$ and 0.5 power

Sensitivity to Luminosity

■ Because measurement averages over entire calorimeter

- Sensitive to # of multiple interactions
 - > instantaneous luminosity
- Take this into account
 - > Typically by including luminosity profile in simulated events
 - > Constrain simulation using real data
 - Example here is $Z \rightarrow e^+e^-$ for W mass measurement

Fake MET Signatures

- **Instrumental effects are largest single source of MET**
 - **Calorimeter misbehaviour**
 - > Hot/warm cells
 - **Cracks in calorimeter**
 - > Especially when you believe there is a jet nearby
- **Other backgrounds come from a host of sources (depending on the analysis):**
 - Cosmic rays, beam halo, beam “splash”

- **In CDF and D0, biggest source of MET comes from “poorly measured” jets**
 - **Two sources**
 - > Statistical fluctuations in energy
 - > Cracks and/or dead regions
 - **Reduce these by rejecting events with MET correlated with large energy deposition (such as a jet)**
 - **Attempting to correct MET for these has not worked particularly well**

Use of MET in Analyses

- MET is primarily used as a measure of νP_T
 - What you DON'T get is the P_z of the neutrino
 - > You don't know x_1 or x_2 of the initial state partons
 - > And life is complicated if there are ≥ 2 ν 's expected

- Lack of P_z motivated introduction of “transverse mass”

$$M_T \equiv \sqrt{2P_T^l E_T (1 - \cos \Delta\phi)}$$

- Virtue is that it is approximately Lorentz-invariant
- Retains significant amount of information in measurements such as M_W
- Use in top dilepton events shows that one can deal with multiple ν final states

Can One Recover P_z ?

■ Traditional way of recovering P_z is to employ kinematic constraints

- In top quark mass measurement, require $l + \text{MET}$ come from W
 - > Constrain to W mass gives quadratic equation in P_z
 - > Solve and choose one solution
 - One algorithm is to choose the most probable one (ie., smallest P_z)

■ Variants of this used in some Top & SUSY analyses

- It doesn't "buy" you a lot because of the integration over the initial state partons

■ One example comes from M_{top} analysis in dilepton events

- Use all kinematic constraints
 - > 23 equations and 24 variables
- Solve for P_z of $t\bar{t}$ system
 - > Independent of M_{top}
- For each event, can define a posteriori probability vs M_{top}
- Product probability used to estimate M_{top}
 - > Bottom line is that it doesn't create more information

Background Considerations

- At very large MET (aside from instrumental effects), most serious backgrounds are “irreducible”

- Physics signatures that produce real MET, e.g.

$$Z + X \rightarrow (\nu\bar{\nu}) + X$$

$$W + X \rightarrow (\tau\bar{\nu}) + X$$

- Several strategies to estimate and control these
 - For invisible Z decays, use $Z \rightarrow l^+l^-$ as control sample
 - Many examples of this technique from CDF & D0

Example: MET in Gluino Search

- **Search for gluino production**
 - Assume sbottom+b decay
 - Look for ≥ 2 b-tagged jets + MET
- **Selection**
 - MET
 - > L1/L2/L3 trigger $> 25/35/45$ GeV
 - Offline MET > 70 GeV
 - Jet cuts
 - > ≥ 2 jets $E_T > 25$ GeV and $|\eta| < 2.4$
 - > Leading jet $E_T > 35$ GeV
 - > At least two b-tags
- **Define three control regions**
 - QCD, Lepton, Pre-optimization
 - > Defined so that should be dominated by SM sources
 - QCD: 2nd jet “aligned” with MET -- $\Delta\phi < 0.4$
 - Lepton: require isolated lepton with $P_T > 10$ GeV
 - Pro-optimization: no alignment of jets with MET and no lepton
 - Check that event rates made sense

CDF Collaboration, arXiv:0903.2618, March 2009

CDF Run II Preliminary 2.5 fb⁻¹

Two Inclusive Tags	QCD Region	Lepton Region	Preoptimization Region
W/Z + jets production	10 ± 7	19 ± 14	29 ± 22
Diboson production	0.4 ± 0.1	2 ± 0.6	4 ± 1
Top pair production	18 ± 6	107 ± 34	140 ± 45
Single top production	1 ± 0.2	4 ± 1	6 ± 1
HF QCD Multijets	864 ± 432	23 ± 11	273 ± 136
Light-flavour contamination	238 ± 48	8 ± 2	57 ± 11
Total expected	1132 ± 435	164 ± 38	510 ± 145
Observed	1104	156	455

SUSY Search Results

- Employ a NN to further discriminate signal from background
 - Trained on pre-optimization region (for background) and MC (for signal)
 - > No evidence of signal
 - > Set limit using NN output
